

# **On the Applicability of Rule-Based Programming to Location Inference**

Katharina Hahn, Kirsten Terfloth,  
Georg Wittenburg, and Jochen Schiller  
Freie Universität Berlin

3. GI KuVS Fachgespräch "Ortsbezogene Anwendungen und Dienste", Berlin, Germany

- Location inference is a fundamental building block for location-based services (LBS).
- Location inference algorithms may work on a variety of input data:
  - GPS coordinates + stored data (e.g. maps, ...)
  - Information from local radio transmissions (e.g. RFID, ...)
  - Information from sensors on the device
- Additionally, a location inference algorithm should
  - follow event-like semantics, and
  - run efficiently on resource constrained devices.

➤ How can location inference be implemented elegantly?

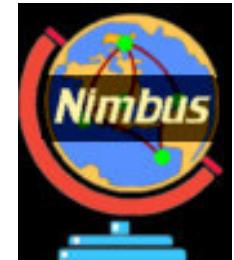

- Rule-based programming naturally suits both
    - diverse input formats, and
    - provides event-like semantics.
  - The FACTS middleware architecture provides a rule engine requiring no more than 8 KB.
- Implement a rule-based location inference algorithm on the FACTS middleware architecture.

- Example: Dating Service
- Conclusion

- Nimbus [1]
  - Platform for location aware applications
  - Mobile fraction
    - Integration of diverse positioning systems
  - Network fraction
    - Resides on decentralized, self-organizing, logically coupled servers
    - Enhancement of location information
  - Nimbus services
    - Provide semantic position (campus), meta-information (wood, building)
    - Location based services (trigger, geocast)
  - Architecture
    - Application layer
    - Service layer
    - Base layer

- Nexus [2]
  - Generic platform to support location aware applications
  - Environmental model
    - Spatial models of physical surrounding
    - Combination of several heterogeneous spatial models
    - Enrichment through virtual objects and services
  - Augmented world model
    - Enhancement of spatial model with virtual information spaces
  - Support context-aware applications and location-based services, among others
    - Location based communication
    - Spatial Events

- TRANSIT [3]
  - Proactive guidance of visitors of Olympics 2008 (Beijing) to their demanded destination
  - Personalized and situation-dependent real-time information supply
  - Components
    - Traffic Information Center
    - Routing Engine
    - Services
- Tourist Information Provider [4]
  - Event Notification in Location-based Services
  - Provide tourists with information of sights based on context
    - Location
    - Personal interests (profile)
    - Travel History
  - TIP Services
    - Recommendation service
    - Map service

- General idea:

A rule consist of a

- Condition part – which circumstances lead to the execution of a rule
- Action part – what actions are undertaken in case a certain state of the system is reached

“ **If** the device reaches state x  
and information about y is available  
**then** trigger the execution of z.”

## Motivation

- Event semantics can be expressed naturally
- Energy-efficient approach for portable devices
  - Reactions to incoming data
  - Low-power mode of device in case no action needed
- Rules are stateless and modular in design
  - Upgrades/changes easily possible at runtime
- Language can be very concise
  - No dissipation of constraint resources
  - Well-suited for small devices

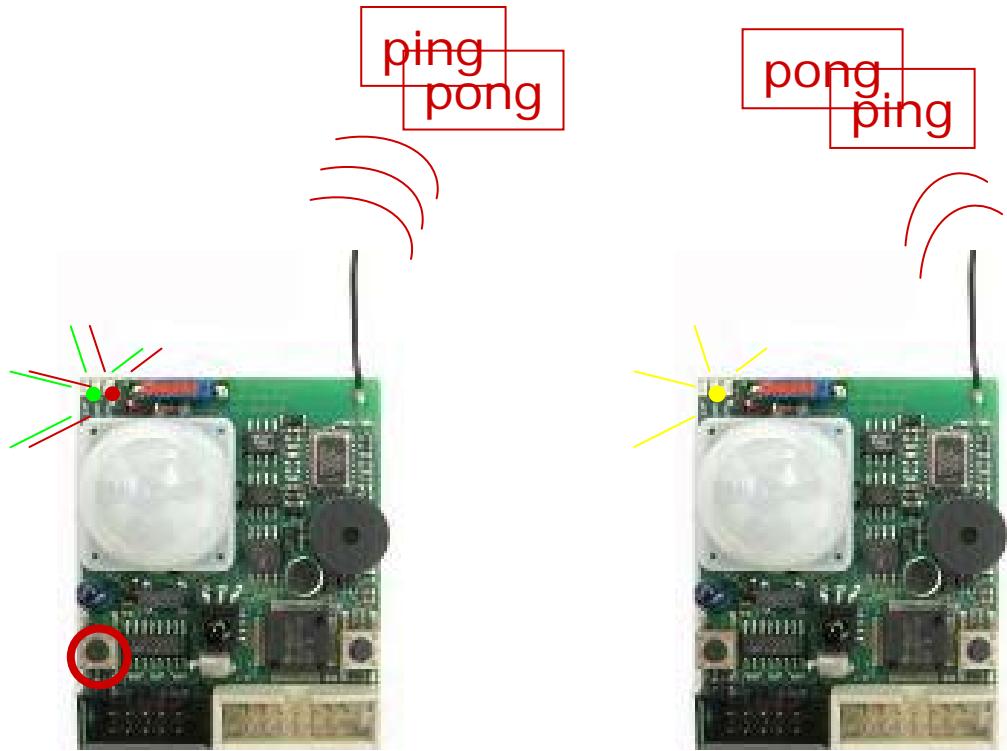

# Example: PingPong ruleset

```
rule button 150
<- exists {button}
-> retract {button}
-> define ping
-> send 0 15 {ping}
-> retract {ping}
-> call toggleGreenLED
```

```
rule ping 100
<- exists {ping}
-> retract {ping}
-> define pong
-> send 0 15 {pong}
-> retract {pong}
-> call toggleYellowLED
```

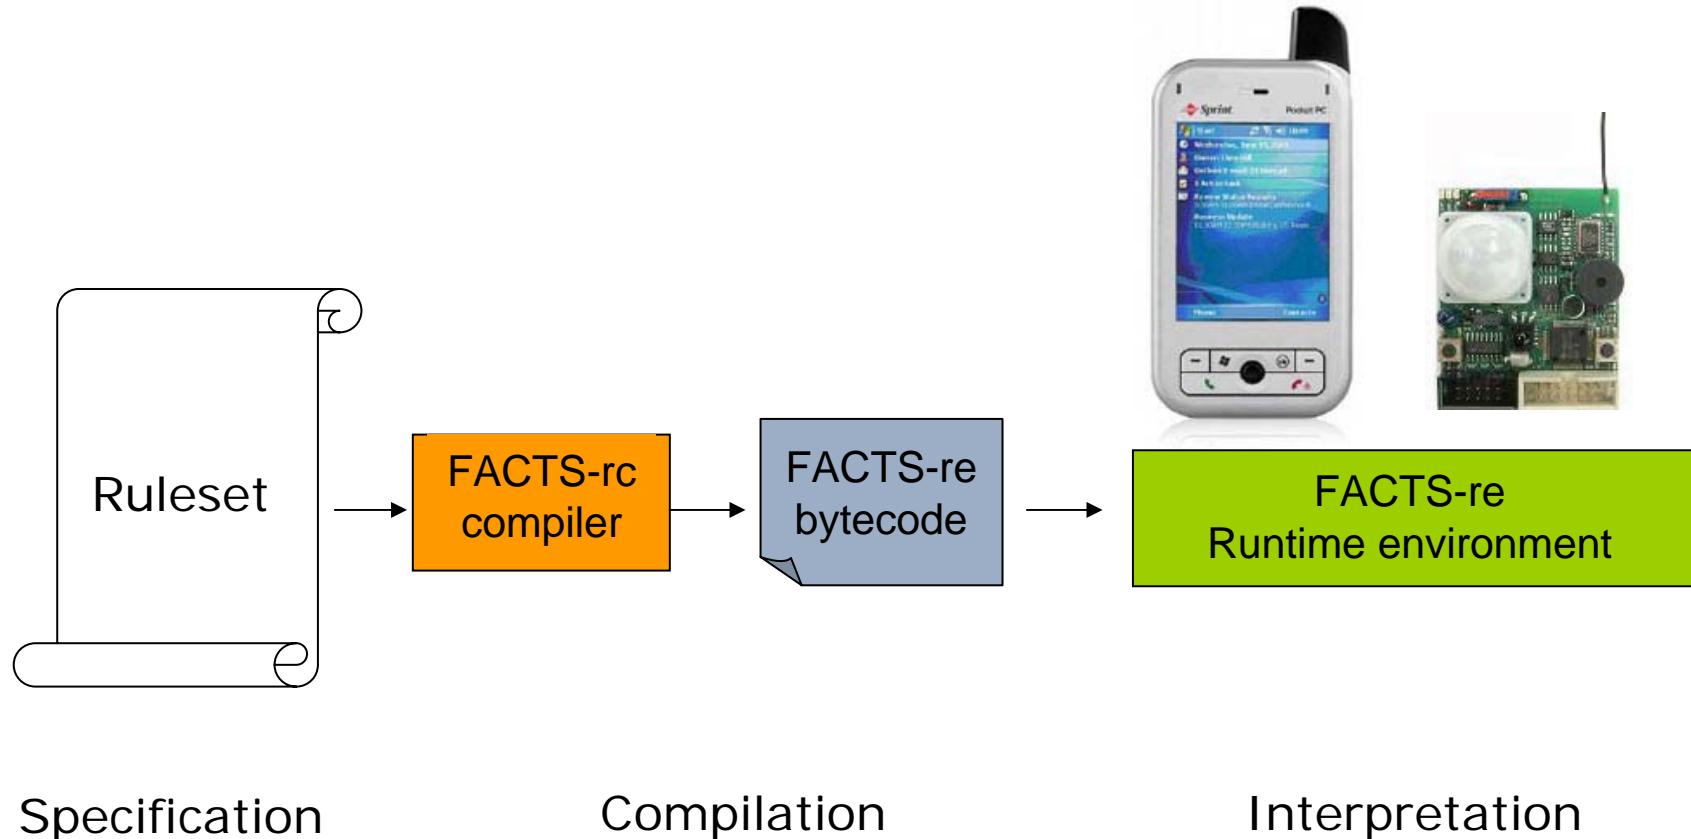

```
rule pong 100
<- exists {pong}
-> retract {pong}
-> call toggleRedLed
```

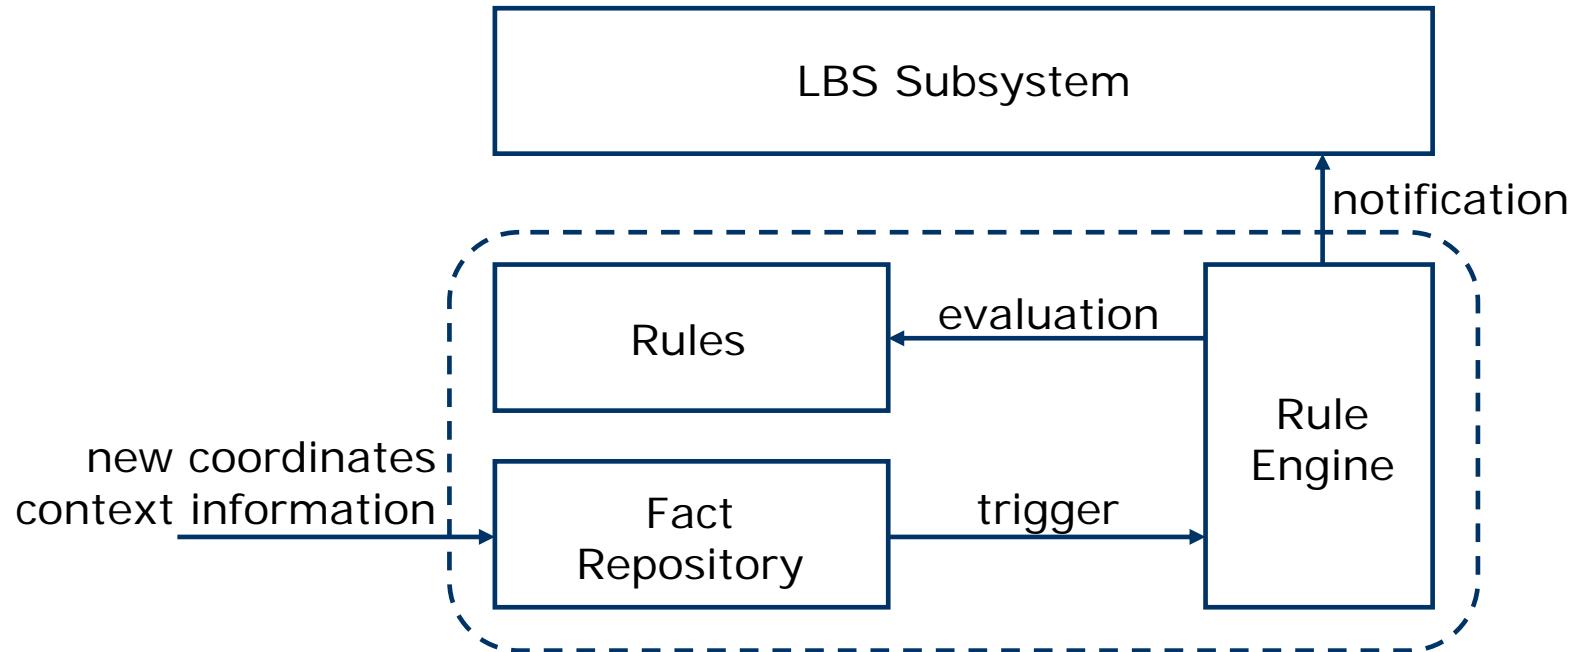

Condition: pong

Condition: ping

- FACTS is a runtime environment for rules which are compiled to bytecode
- Building blocks:
  - Facts – Representation of any data in the system (state, sensor readings, global variables, etc.)
  - Rules – Specification of algorithms for data processing
  - Functions – Support for native code
- Advantages:
  - Inherent energy efficiency
  - Sandboxed execution environment prevents runtime failures due to managed memory access
  - Uniform data representation abstracts from underlying layers
    - Radio interface
    - Sensor hardware

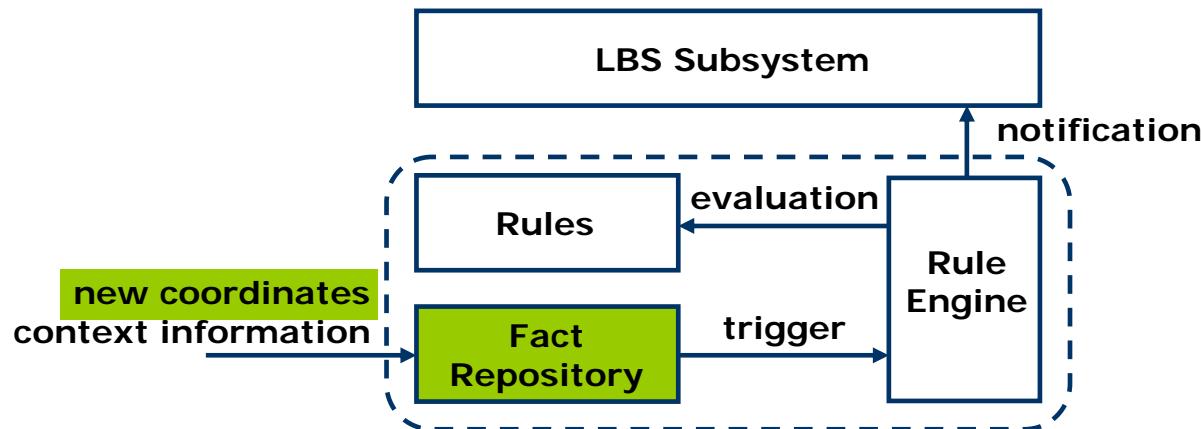

1. Data (sensor data/radio packets/etc.) is received
  - ➔ Formating of this data into facts abstraction  
(named data-value pairs)
  - ➔ Triggering of the rule engine
2. Rule engine checks conditions of available rules
  - ➔ Match of rule condition to available facts leads to rule execution
  - ➔ In case no match is found, the system stays quiet
3. Rules may produce new facts, thus trigger other rules
4. Rule execution stops when no modification to the fact repository has been performed in the last round.

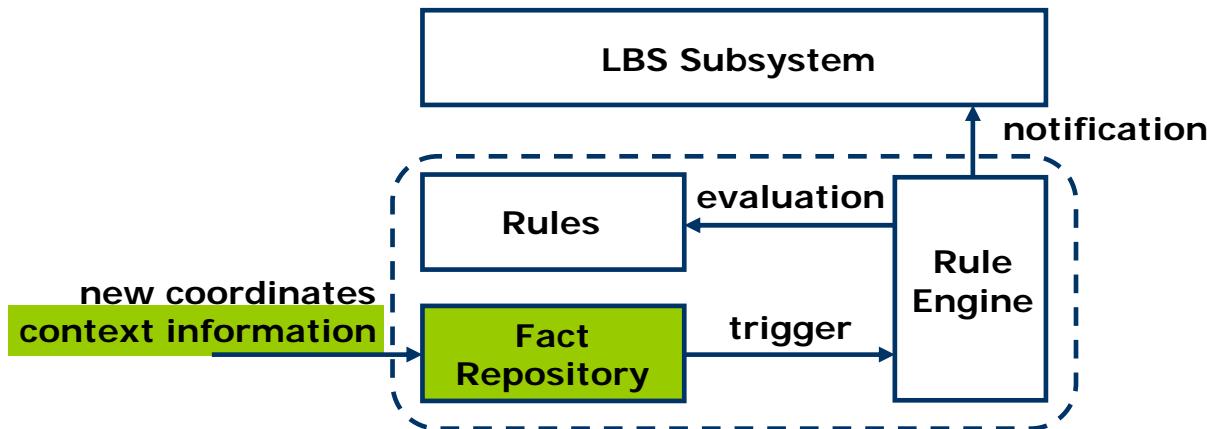

- Precise location matching
  - Sensor provides location information
  - Match location information to semantic location through previously defined fact
  - Fact location [N=52°30.62, E=13°24.97, place = „Goya“]

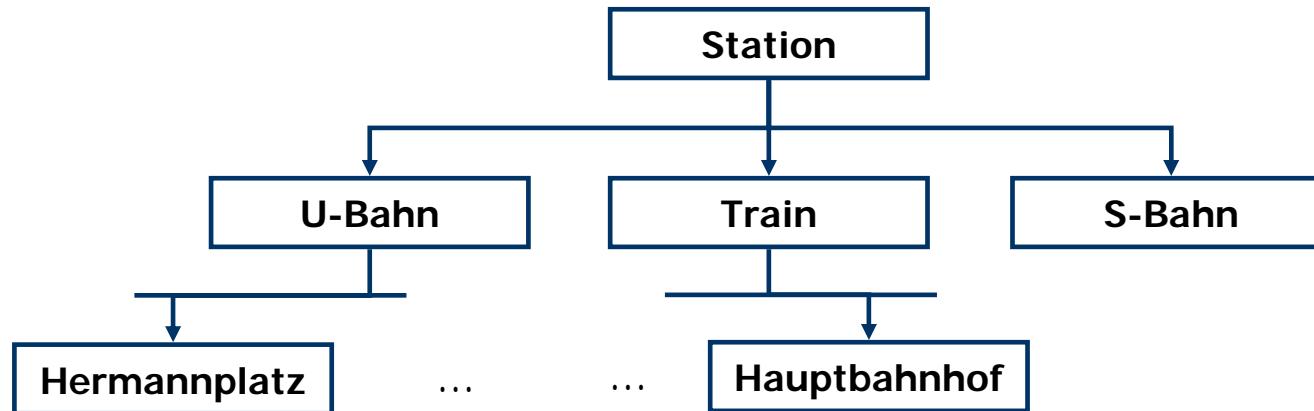

- Abstract Location Matching
  - Inference of *Abstract Location* through
    - Precise location
    - Additional environmental sensors
  - Generalization of precise locations
    - Whenever precise location matching not possible
  - fact context [place = „Goya“ type = „night club“]

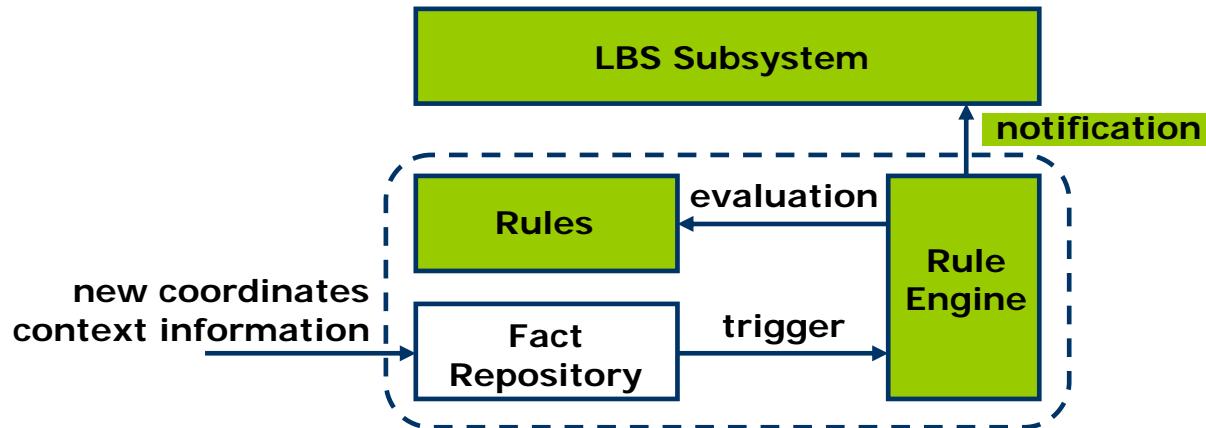

- Location Hierarchy
  - Define rule at super class
  - Sub-classes inherit rules of their abstract (super) classes
  - Prevention of multiple definition of one rule for several classes
- Example services:
  - Station: ticket share
  - Hauptbahnhof: Display time table

- Service Trigger
  - Services are triggered according to previously defined rules within the rule engine
  - Easy to add as rules to rule engine
  - System easy to expand for application programmer

# Example: Dating Service (1)

```
fact location [  
    long = "N52_29_91",  
    lat = "E13_21_15",  
    place = "Goya_Club"  
]
```

```
fact context [  
    place = "Goya_Club",  
    type = "Night_Club"  
]
```

```
fact coordinate [  
    long = "N52_29_91",  
    lat = "E13_21_15"  
]
```

```
fact currentLocation [  
    place = "Goya_Club"  
]
```

```
fact currentContext [  
    type = "Night_Club"  
]
```

```
rule updateLocation 200  
<- exists {coordinate}  
> retract {currentLocation}  
> define currentLocation [place = {location place  
    <- eval ({this long} == newCoordinateLong)  
    <- eval ({this lat} == newCoordinateLat)  
}]  
> retract {coordinate}  
  
rule updateContext 190  
<- exists {currentLocation}  
> retract {currentContext}  
> define currentContext [type = {context type  
    <- eval ({this place} == {currentLocation place})}  
}]
```

# Example: Dating Service (2)

```
fact personalData [  
    gender = "m",  
    age = 26  
]
```

```
fact datingProfile [  
    gender = "f",  
    minAge = 20,  
    maxAge = 30  
]
```

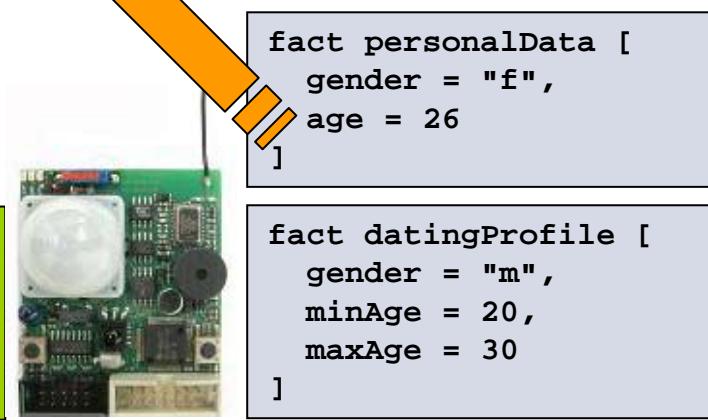

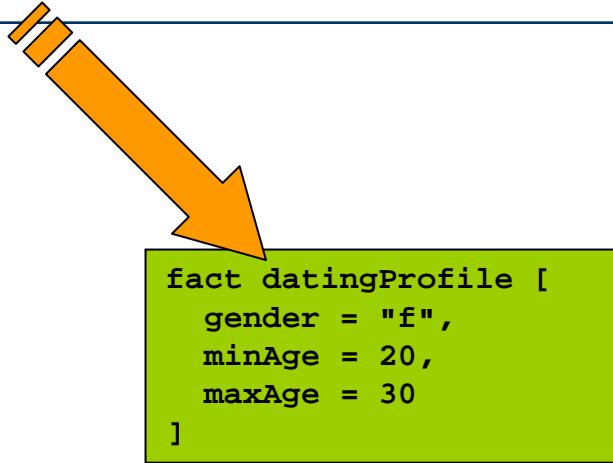

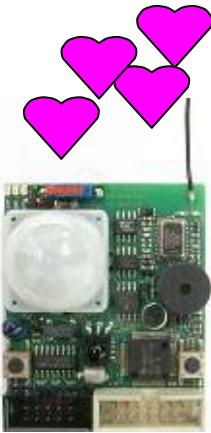

```
fact currentContext [  
    type = "Night_Club"  
]
```

```
fact datingServiceActive
```

```
fact periodicBroadcastTrigger
```

```
rule activateDatingService 100  
<- eval ({currentContext type} == "Night_Club")  
-> define datingServiceActive  
-> call defineLater ({periodicBroadcastTrigger}, 60)  
  
rule broadcastMyDatingProfile 90  
<- exists {datingServiceActive}  
<- exists {periodicBroadcastTrigger}  
-> send systemBroadcast systemTxRange {datingProfile  
    <- eval ({this owner} == systemID)  
}  
-> call defineLater ({periodicBroadcastTrigger}, 60)
```

# Example: Dating Service (3)

```
rule replyToDatingProfile 80  
<- exists {datingServiceActive}  
<- exists {datingProfile  
            <- eval ({this owner} != systemID)  
            <- eval ({this gender} == {personalData gender})  
            <- eval ({this minAge} <= {personalData age})  
            <- eval ({this maxAge} >= {personalData age})  
        }  
        -> send {datingProfile owner  
                  <- eval ({this owner} != systemID)  
              } systemTxRange {personalData}  
        -> retract {datingProfile  
                    <- eval ({this owner} != systemID)  
                }
```

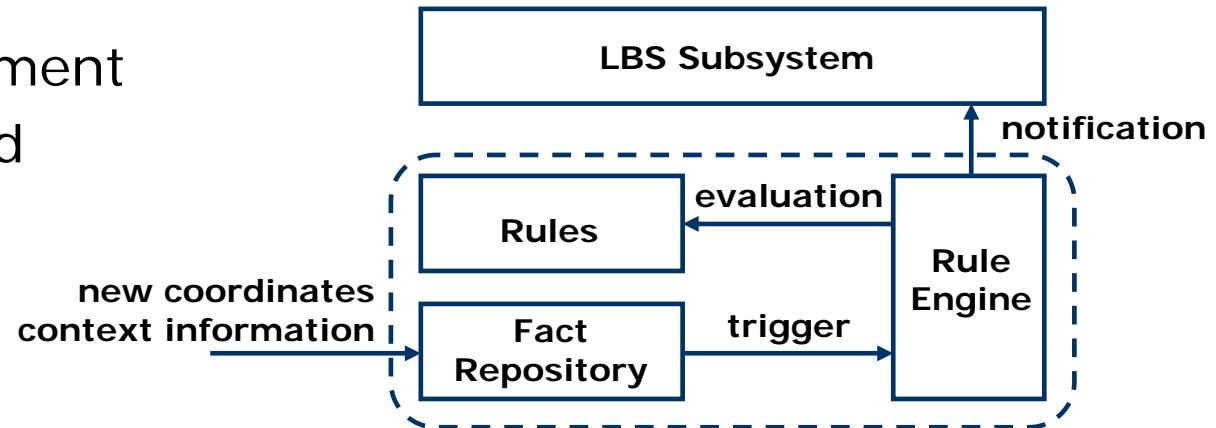

- Simple rule-based location inference algorithm in:

	unoptimized		optimized	
	#	size (B)	#	size (B)
<b>Rules</b>	5	60	5	60
<b>Conditions</b>	21	126	16	96
<b>Statements</b>	11	88	11	88
<b>Slots</b>	50	400	29	232
<b>Expressions</b>	40	240	24	144
<b>Initializers</b>	2	8	2	8
<b>Variables</b>	40	160	24	96
<b>Facts</b>	7	140	7	140
<b>Properties</b>	17	102	17	102
<b>TOTAL</b>		<b>1,324</b>		<b>966</b>

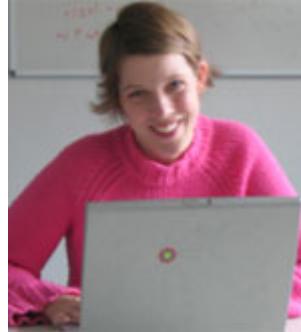

- Rule-based Event Notification on FACTS
- FACTS: rule-based middleware
  - Small size
  - Deployment on sensor nodes
- Interface of services and middleware
  - Through facts in fact repository
  - Rules in application-level ruleset
- → easy to implement
- → easy to extend

- Porting of FACTS to end-user devices
- Automated configuration environment
  - Support for context fact definition
  - Support for rule specification

# Thank you!

```
fact datingProfile [  
    gender = "m",  
    minAge = 25,  
    maxAge = 35  
]
```

```
fact datingProfile [  
    gender = "m",  
    minAge = 18,  
    maxAge = 25  
]
```

```
fact datingProfile [  
    gender = "f",  
    minAge = 20,  
    maxAge = 30  
]
```
